INTRODUCTION

Determination of the optimum stage at which to harvest a fish stock for either maximum poundage or dollar yield is a complex problem. Although it may be shifted by special limitations inherent to the harvest gear type such as lack of selectivity, this stage generally occurs near where the biomass of marketable-size individuals is at a maximum, i.e. where gains from recruitment and growth are just being overtaken by losses from natural and fishing-induced (non-harvest) mortality.

Available biomass of pink shrimp, *Pandalus jordani*, appears to be first a function of year-class strength, i.e. number of individuals produced and surviving, and then of growth rates. These parameters may not be independent. Growth may be related to rate of sex change from male to female which in turn affects stock fecundity. Mortality rates may be related to age or to stock size.

Evaluation of these production parameters requires detailed data on stock sex, age, and size composition over time. These parameters must be compared between areas or "beds" to determine variability between areas or even if discrete stocks exist.

Personnel of the Oregon Department of Fish and Wildlife^{1/} have sampled pink shrimp catches from exploratory, survey, and commercial fishing since 1951. Data collected include carapace length, sex, females ovigerous, and average size (shrimp per pound) by area and time period.

This information is used to estimate age composition, sex composition and timing of sex change from male to female, growth and spawning period. Robinson and Milburn (1967) summarized this material by month and area of

^{1/} Previously Fish Commission of Oregon

catch for the period 1951-1965, and this report will do the same for the period 1966-1980.

Tables presented include length-frequency by sex by month, area, and year. Number and size of samples utilized, average size of shrimp in shrimp per pound, and age and sex percent composition are also provided. Also we provide frequency polygons opposite each data set for visual evaluation of growth and age composition by sex.

SOURCES OF INFORMATION

Most of the data presented here came from market sampling of commercial shrimp landings. Data on area of catch came from commercial fishermen's logbooks, and catch area designations are shown in Figure 1. Another source of samples was shrimp abundance survey cruises conducted by Oregon Department of Fish and Wildlife personnel on chartered commercial shrimp trawl vessels.

All available shrimp biological samples were examined and those with any of the following shortcomings were omitted:

- (1) individuals not sexed
- (2) individuals not measured for length
- (3) area of catch not available
- (4) weight of sample not available
- (5) sample with shrimp from more than one area
- (6) sample not used by original collector^{2/}; unless simply taken after original summary completed

METHODS

Samples were obtained and processed following the methods used and described earlier by Robinson and Milburn (1967), except that carapace length measurements were recorded in 0.2 millimeter increments only through 1967. Starting in 1968, measurements were recorded to the nearest lower 0.5 millimeter. All 1966 and 1967 length data were converted to this increment for

^{2/} We assumed that the original sampler had a valid reason for rejecting the sample at that time.

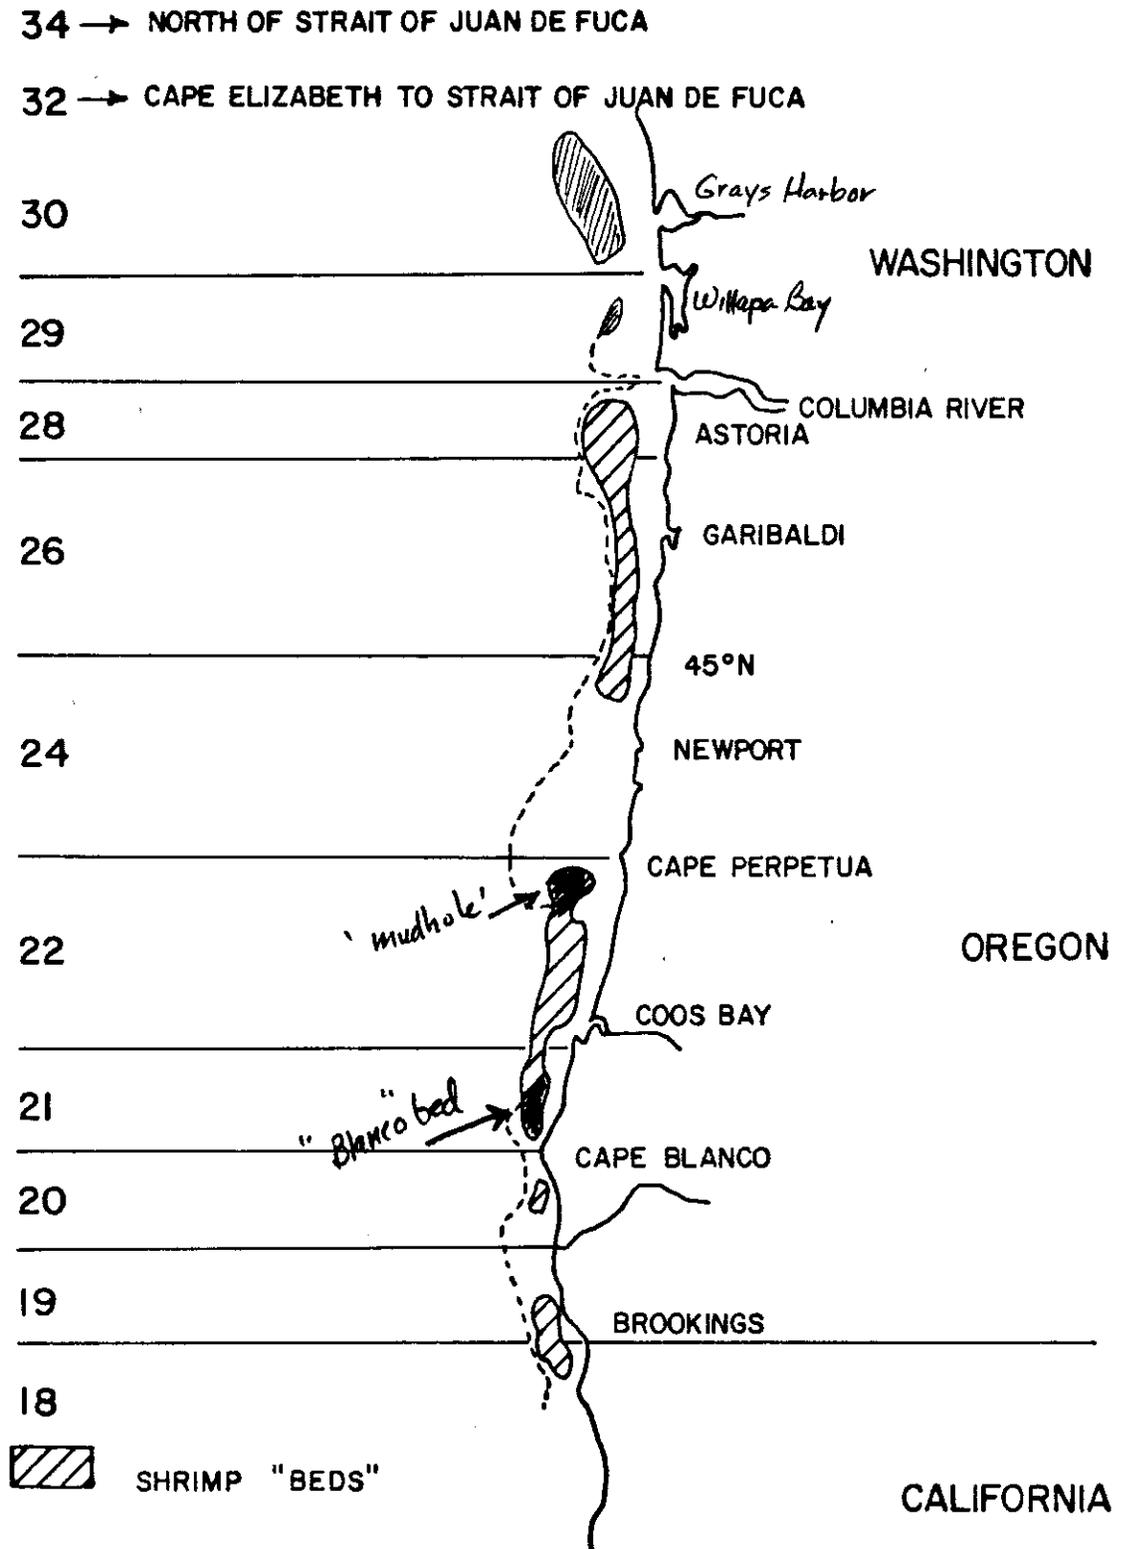

FIGURE 1. Area designations for shrimp caught off or landed in Oregon.

consistency in this report.

Sampling was conducted on a regular basis by department personnel at the major shrimp landing ports of Astoria, Newport, Coos Bay, and Brookings. Individual sample sizes approximated 100 shrimp. Sex was determined by close examination of the inner ramus of the first pleopod after Tegelberg and Smith (1957), and sample weights were recorded to the nearest gram. Age group allocation was determined by examination of graphed length frequency polygons. Frequency peaks were assigned ages 0, I, II, or III+ based on relative size and position over time, and age classes were separated where frequencies were lowest between peaks.

Length frequency distributions by year, area, and month are presented in Table 1 and corresponding graphical representations of length frequency (in percent) are shown in Figure 2. Sample sex and age frequency in percent and shrimp size (shrimp per pound) by year, area, and month are presented in Table 2.
